

# Mixed Model

# Mixed Model Analysis

Basic model:

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\mathbf{u} + \mathbf{e},$$

where

$\mathbf{X}$  is a  $n \times p$  model matrix of known constants

$\boldsymbol{\beta}$  is a  $p \times 1$  vector of *fixed* unknown parameter values

$\mathbf{Z}$  is a  $n \times q$  model matrix of known constants

$\mathbf{u}$  is a  $q \times 1$  random vector

$\mathbf{e}$  is a  $n \times 1$  vector of random errors

with

$$E(\mathbf{e}) = \mathbf{0} \quad \text{Var}(\mathbf{e}) = R$$

$$E(\mathbf{u}) = \mathbf{0} \quad \text{Var}(\mathbf{u}) = G$$

$$\text{Cov}(\mathbf{e}, \mathbf{u}) = 0$$

Then

$$\begin{aligned} E(\mathbf{Y}) &= E(X\boldsymbol{\beta} + Z\mathbf{u} + \mathbf{e}) \\ &= X\boldsymbol{\beta} + ZE(\mathbf{u}) + E(\mathbf{e}) \\ &= X\boldsymbol{\beta} \end{aligned}$$

$$\begin{aligned} \text{Var}(\mathbf{Y}) &= \text{Var}(X\boldsymbol{\beta} + Z\mathbf{u} + \mathbf{e}) \\ &= \text{Var}(Z\mathbf{u}) + \text{Var}(\mathbf{e}) \\ &= ZGZ^T + R \end{aligned}$$

# Normal-Theory Mixed Model

$$\begin{bmatrix} \mathbf{u} \\ \mathbf{e} \end{bmatrix} \sim N \left( \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix}, \begin{bmatrix} G & 0 \\ 0 & R \end{bmatrix} \right)$$

Then,

$$\mathbf{Y} \sim N(X\beta, \underline{ZGZ^T + R})$$

↑

call this  $\Sigma$

## Example 9.1: Random Blocks

Comparison of four processes for producing penicillin

<i>Process A</i>	}	Levels of a “fixed” treatment factor
<i>Process B</i>		
<i>Process C</i>		
<i>Process D</i>		

Blocks correspond to different batches of an important raw material,  
corn steep liquor

- Random sample of five batches
- Split each batch into four parts:
  - ▶ run each process on one part
  - ▶ randomize the order in which the processes are run within each batch

Here, batch effects are considered as *random* block effects:

- Batches are sampled from a population of many possible batches
- To repeat this experiment you would need to use a different set of batches of raw material

Data Source: Box, Hunter & Hunter (1978), *Statistics for Experimenters*. (Wiley & Sons, New York).

Data file:            `penclln.dat`

SAS code:            `penclln.sas`

R code:              `penclln.r`

Model:

$$Y_{ij} = \mu + \alpha_i + \beta_j + e_{ij}$$

$\uparrow$                        $\uparrow$                        $\uparrow$                        $\uparrow$   
 Yield for the              mean yield              random batch              random error  
*i*-th process              for the              effect  
 applied              *i*-th process,  
 to the              averaging  
*j*-th batch              across the  
    entire population  
    of possible  
    batches

where

$$\beta_j \sim NID(0, \sigma_\beta^2), \quad e_{ij} \sim NID(0, \sigma_e^2)$$

and any  $e_{ij}$  is independent of any  $\beta_j$ .

Here

$$\begin{aligned}\mu_i = E(Y_{ij}) &= E(\mu + \alpha_i + \beta_j + e_{ij}) \\ &= \mu + \alpha_i + E(\beta_j) + E(e_{ij}) \\ &= \mu + \alpha_i \quad i = 1, 2, 3, 4\end{aligned}$$

represents the mean yield for the  $i$ -th process, averaging across all possible batches.

PROC GLM and PROC MIXED in SAS fit a restricted model with  $\alpha_4 = 0$ . Then

- $\mu = \mu_4$  is the mean yield for process D
- $\alpha_i = \mu_i - \mu_4 \quad i = 1, 2, 3, 4$ .

In R you could use the *treatment* constraints where  $\alpha_1 = 0$ . Then

- $\mu = \mu_1$  is the mean yield for process A
- $\alpha_i = \mu_i - \mu_1 \quad i = 1, 2, 3, 4.$

Alternatively, you could choose the solution to the normal equations given by *sum* constraints

- $\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4 = 0$
- $\mu = (\mu_1 + \mu_2 + \mu_3 + \mu_4)/4$
- $\alpha_i = \mu_i - \mu$  is the difference between the mean yield for the  $i$ -th process and the overall mean yield.

Variance-covariance structure:

$$\begin{aligned}\text{Var}(Y_{ij}) &= \text{Var}(\mu + \alpha_i + \beta_j + e_{ij}) \\ &= \text{Var}(\beta_j + e_{ij}) \\ &= \text{Var}(\beta_j) + \text{Var}(e_{ij}) \\ &= \sigma_\beta^2 + \sigma_e^2 \quad \text{for all } (i, j)\end{aligned}$$

Different runs on the same batch:

$$\begin{aligned}\text{Cov}(Y_{ij}, Y_{kj}) &= \text{Cov}(\mu + \alpha_i + \beta_j + e_{ij}, \mu + \alpha_k + \beta_j + e_{kj}) \\ &= \text{Cov}(\beta_j + e_{ij}, \beta_j + e_{kj}) \\ &= \text{Cov}(\beta_j, \beta_j) + \text{Cov}(\beta_j, e_{kj}) + \text{Cov}(e_{ij}, \beta_j) + \text{Cov}(e_{ij}, e_{kj}) \\ &= \text{Var}(\beta_j) \\ &= \sigma_\beta^2 \quad \text{for all } i \neq k\end{aligned}$$

Correlation among yields for runs on the same batch:

$$\begin{aligned}\rho &= \frac{\text{Cov}(Y_{ij}, Y_{kj})}{\sqrt{\text{Var}(Y_{ij})\text{Var}(Y_{kj})}} \\ &= \frac{\sigma_{\beta}^2}{\sigma_{\beta}^2 + \sigma_e^2} \text{ for } i \neq k\end{aligned}$$

Results for runs on different batches are uncorrelated (independent):

$$\text{Cov}(Y_{ij}, Y_{k\ell}) = 0 \quad \text{for } j \neq \ell$$

Results from the four runs on a single batch:

$$\text{Var} \begin{bmatrix} Y_{1j} \\ Y_{2j} \\ Y_{3j} \\ Y_{4j} \end{bmatrix} = \begin{bmatrix} \sigma_{\beta}^2 + \sigma_e^2 & \sigma_{\beta}^2 & \sigma_{\beta}^2 & \sigma_{\beta}^2 \\ \sigma_{\beta}^2 & \sigma_{\beta}^2 + \sigma_e^2 & \sigma_{\beta}^2 & \sigma_{\beta}^2 \\ \sigma_{\beta}^2 & \sigma_{\beta}^2 & \sigma_{\beta}^2 + \sigma_e^2 & \sigma_{\beta}^2 \\ \sigma_{\beta}^2 & \sigma_{\beta}^2 & \sigma_{\beta}^2 & \sigma_{\beta}^2 + \sigma_e^2 \end{bmatrix}$$
$$= \sigma_{\beta}^2 J + \sigma_e^2 I$$

This special type of covariance structure is called *compound symmetry*.

Write this model as  $\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\mathbf{u} + \mathbf{e}$

$$\begin{bmatrix} Y_{11} \\ Y_{21} \\ Y_{31} \\ Y_{41} \\ Y_{12} \\ Y_{22} \\ Y_{32} \\ Y_{42} \\ Y_{13} \\ Y_{23} \\ Y_{33} \\ Y_{43} \\ Y_{14} \\ Y_{24} \\ Y_{34} \\ Y_{44} \\ Y_{15} \\ Y_{25} \\ Y_{35} \\ Y_{45} \end{bmatrix} = \begin{bmatrix} 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \mu \\ \alpha_1 \\ \alpha_2 \\ \alpha_3 \\ \alpha_4 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \\ \beta_4 \\ \beta_5 \end{bmatrix} + \begin{bmatrix} e_{11} \\ e_{21} \\ e_{31} \\ e_{41} \\ e_{12} \\ e_{22} \\ e_{32} \\ e_{42} \\ e_{13} \\ e_{23} \\ e_{33} \\ e_{43} \\ e_{14} \\ e_{24} \\ e_{34} \\ e_{44} \\ e_{15} \\ e_{25} \\ e_{35} \\ e_{45} \end{bmatrix}$$

Here

$$G = \text{Var}(\mathbf{u}) = \sigma_B^2 I_{5 \times 5}$$

$$R = \text{Var}(\mathbf{e}) = \sigma_e^2 I_{n \times n}$$

and

$$\text{Var}(\mathbf{Y}) = \text{Var}(X\beta + Z\mathbf{u} + \mathbf{e})$$

$$= \text{Var}(Z\mathbf{u}) + \text{Var}(\mathbf{e})$$

$$= ZGZ^T + R$$

$$= \sigma_\beta^2 ZZ^T + \sigma_e^2 I$$

$$= \begin{bmatrix} \sigma_\beta^2 J + \sigma_e^2 I & & & \\ & \sigma_\beta^2 J + \sigma_e^2 I & & \\ & & \ddots & \\ & & & \sigma_\beta^2 J + \sigma_e^2 I \end{bmatrix}$$

## Example 9.2: Hierarchical Random Effects Model

Analysis of sources of variation in a process used to monitor the production of a pigment paste.

### Current Procedure:

- Sample barrels of pigment paste
- One sample from each barrel
- Send the sample to a lab for determination of moisture content

Measured Response: ( $Y$ ) moisture content of the pigment paste (units of one tenth of 1%).

Problem: Variation in moisture content is too large

- average moisture content is approximately 25 (or 2.5%)
- standard deviation of about 6

Examine sources of variation:

## Data Collection: Hierarchical (or nested) Study Design

- Sample  $b$  barrels of pigment paste
- $s$  samples are taken from the content of each barrel
- Each sample is mixed and divided into  $r$  parts. Each part is sent to the lab.

There are  $n = (b)(s)(r)$  observations.

Model:

$$Y_{ijk} = \mu + \beta_i + \delta_{ij} + e_{ijk}$$

where

$Y_{ijk}$  is the moisture content determination for the  $k$ -th part of the  $j$ -th sample from the  $i$ -th barrel

$\mu$  is the mean moisture content

$\beta_i$  is a random barrel effect:

$$\beta_i \sim NID(0, \sigma_\beta^2)$$

$\delta_{ij}$  is a random sample effect:

$$\delta_{ij} \sim NID(0, \sigma_\delta^2)$$

$e_{ijk}$  corresponds to random measurement error:

$$e_{ijk} \sim NID(0, \sigma_e^2)$$

## Covariance Structure

Homogeneous variances:

$$\begin{aligned} \text{Var}(Y_{ijk}) &= \text{Var}(\mu + \beta_i + \delta_{ij} + e_{ijk}) \\ &= \text{Var}(\beta_i) + \text{Var}(\delta_{ij}) + \text{Var}(e_{ijk}) \\ &= \sigma_\beta^2 + \sigma_\delta^2 + \sigma_e^2 \end{aligned}$$

Two parts of one sample:

$$\begin{aligned} &\text{Cov}(Y_{ijk}, Y_{ij\ell}) \\ &= \text{Cov}(\mu + \beta_i + \delta_{ij} + e_{ijk}, \mu + \beta_i + \delta_{ij} + e_{ij\ell}) \\ &= \text{Cov}(\beta_i, \beta_i) + \text{Cov}(\delta_{ij}, \delta_{ij}) \\ &= \sigma_\beta^2 + \sigma_\delta^2 \quad \text{for } k \neq \ell \end{aligned}$$

Observations on different samples taken from the same barrel:

$$\begin{aligned}\text{Cov}(Y_{ijk}, Y_{iml}) &= \text{Cov}(\mu + \beta_i + \delta_{ij} + e_{ijk}, \mu + \beta_i + \delta_{im} + e_{iml}) \\ &= \text{Cov}(\beta_i, \beta_i) \\ &= \sigma_\beta^2 \quad j \neq m\end{aligned}$$

Observations from different barrels:

$$\text{Cov}(Y_{ijk}, Y_{cml}) = 0, \quad i \neq c$$

## In this study

$b = 15$  barrels were sampled

$s = 2$  samples were taken from each barrel

$r = 2$  sub-samples were analyzed from each sample taken from each barrel

Data file: pigment.dat

SAS code: pigment.sas

R code: pigment.r

Write this model in the form:

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\mathbf{u} + \mathbf{e}$$

$$\begin{bmatrix} Y_{111} \\ Y_{112} \\ Y_{121} \\ Y_{122} \\ Y_{211} \\ Y_{212} \\ Y_{221} \\ Y_{222} \\ \vdots \\ \vdots \\ Y_{15,1,1} \\ Y_{15,1,2} \\ Y_{15,2,1} \\ Y_{15,2,2} \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ \vdots \\ \vdots \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} [\mu] + \begin{bmatrix} 1 & 0 & \dots & 0 & 1 & 0 & 0 & 0 & \dots & 0 & 0 \\ 1 & 0 & \dots & 0 & 1 & 0 & 0 & 0 & \dots & 0 & 0 \\ 1 & 0 & \dots & 0 & 0 & 1 & 0 & 0 & \dots & 0 & 0 \\ 1 & 0 & \dots & 0 & 0 & 1 & 0 & 0 & \dots & 0 & 0 \\ 0 & 1 & \dots & 0 & 0 & 0 & 1 & 0 & \dots & 0 & 0 \\ 0 & 1 & \dots & 0 & 0 & 0 & 1 & 0 & \dots & 0 & 0 \\ 0 & 1 & \dots & 0 & 0 & 0 & 0 & 1 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \dots & 1 & 0 & 0 & 0 & 0 & \dots & 1 & 0 \\ 0 & 0 & \dots & 1 & 0 & 0 & 0 & 0 & \dots & 1 & 0 \\ 0 & 0 & \dots & 1 & 0 & 0 & 0 & 0 & \dots & 0 & 1 \\ 0 & 0 & \dots & 1 & 0 & 0 & 0 & 0 & \dots & 0 & 1 \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \vdots \\ \beta_{15} \\ \delta_{1,1} \\ \delta_{1,2} \\ \delta_{2,1} \\ \delta_{2,2} \\ \vdots \\ \vdots \\ \delta_{15,1} \\ \delta_{15,2} \end{bmatrix} + \mathbf{e}$$

where

$$R = \text{Var}(\mathbf{e}) = \sigma_e^2 \mathbf{I}, \quad G = \text{Var}(\mathbf{u}) = \begin{bmatrix} \sigma_\beta^2 \mathbf{I} & 0 \\ 0 & \sigma_\delta^2 \mathbf{I} \end{bmatrix}$$

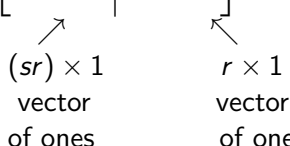

Then

$$E(\mathbf{Y}) = X\beta = \mathbf{1}\mu$$

$$\begin{aligned} \text{Var}(\mathbf{Y}) &= \Sigma = ZGZ^T + R = Z \begin{bmatrix} \sigma_\beta^2 \mathbf{I}_b & 0 \\ 0 & \sigma_\delta^2 \mathbf{I}_{bs} \end{bmatrix} Z^T + \sigma_e^2 \mathbf{I}_{bsr} \\ &= \sigma_\beta^2 (\mathbf{I}_b \otimes J_{sr}) + \sigma_\delta^2 (\mathbf{I}_{bs} \otimes J_r) + \sigma_e^2 \mathbf{I}_{bsr} \end{aligned}$$

because

$$Z = \left[ \begin{array}{c|c} \mathbf{I}_b \otimes \mathbf{1}_{sr} & \mathbf{I}_{bs} \otimes \mathbf{1}_r \end{array} \right]$$

$(sr) \times 1$  vector of ones       $r \times 1$  vector of ones

**Example 9.3** A split-plot experiment with whole plots arranged in blocks.

Blocks:  $r = 4$  fields (or locations).

Whole plots: Each field is divided into  $a = 2$  whole plots.

Whole plot factor: two cultivars of grasses (A, B)

- within each block, cultivar A is grown in one whole plot, cultivar B is grown in the other
- separate random assignments of cultivars to whole plots is done in each block

## Sub-plot factor:

$b = 3$  bacterial inoculation treatments:

CON for control (no inoculation)

DEA for dead

LIV for live

Each whole plot is split into three sub-plots and independent random assignments of inoculation treatments to sub-plots are done within whole plots.

Measured response:

Dry weight yield

Source:

Littel, R.C. Freund, R.J. and Spector, P.C. (1991) SAS Systems for Linear Models, 3rd edition, SAS Institute, Cary, NC

Data: grass.dat

SAS code: grass.sas

S-PLUS code: grass.r

## Block 1

Cultivar B	CON	DEA	LIV
Cultivar A	LIV	CON	DEA

## Block 2

DEA	LIV
LIV	CON
CON	DEA
Cultivar A	Cultivar B

## Block 3

DEA	CON
CON	DEA
LIV	LIV
Cultivar B	Cultivar A

## Block 4

LIV	DEA	CON	Cultivar B
CON	DEA	LIV	Cultivar A

Model with random block effects:

$$Y_{ijk} = \mu + \alpha_i + \beta_j + \eta_{ij} + \gamma_k + \delta_{ik} + e_{ijk},$$

$$i = 1, \dots, a, \quad j = 1, \dots, r, \quad k = 1, \dots, b,$$

$Y_{ijk} \Rightarrow$  observed yield for the  $k$ -th inoculant applied to the  $i$ -th cultivar in the  $j$ -th field

$\alpha_i \Rightarrow$  fixed cultivar effect

$\gamma_k \Rightarrow$  fixed inoculant effect

$\delta_{ik} \Rightarrow$  cultivar\*inoculant interaction

The following random effects are independent of each other:

$\beta_j \sim NID(0, \sigma_\beta^2) \Rightarrow$  random block effects

$\eta_{ij} \sim NID(0, \sigma_w^2) \Rightarrow$  random whole plot effects

$e_{ijk} \sim NID(0, \sigma_e^2) \Rightarrow$  random errors

## Example 9.4: Repeated Measures

In an exercise therapy study, subjects were assigned to one of three weightlifting programs

- (i=1) The number of repetitions of weightlifting was increased as subjects became stronger (RI)
- (i=2) The amount of weight was increased as subjects became stronger (WI)
- (i=3) Subjects did not participate in weightlifting (XCont)

Measurements of strength ( $Y$ ) were taken on days 2, 4, 6, 8, 10, 12 and 14 for each subject.

Source: Littell, Freund, and Spector (1991) SAS System for Linear Models

Data: weight2.dat

SAS code: weight2.sas

R code: weight2.r

## Mixed model

$$Y_{ijk} = \mu + \alpha_i + S_{ij} + \tau_k + \gamma_{ik} + e_{ijk}$$

$Y_{ijk}$  strength measurement at the  $k$ -th time point for the  $j$ -th subject in the  $i$ -th program

$\alpha_i$  *fixed* program effect

$S_{ij}$  random subject effect

$\tau_k$  *fixed* time effect

$e_{ijk}$  random error

where the random effects are all independent and

$$S_{ij} \sim NID(0, \sigma_S^2), \quad e_{ijk} \sim NID(0, \sigma_\epsilon^2)$$

Average strength after  $2k$  days on the  $i$ -th program is

$$\begin{aligned}\mu_{ik} &= E(Y_{ijk}) \\ &= E(\mu + \alpha_i + S_{ij} + \tau_k + \gamma_{ik} + e_{ijk}) \\ &= \mu + \alpha_i + E(S_{ij}) + \tau_k + \gamma_{ik} + E(e_{ijk}) \\ &= \mu + \alpha_i + \tau_k + \gamma_{ik}\end{aligned}$$

for  $i = 1, 2, 3$  and  $k = 1, 2, \dots, 7$ . The variance of any single observation is

$$\begin{aligned}\text{Var}(Y_{ijk}) &= \text{Var}(\mu + \alpha_i + S_{ij} + \tau_k + \gamma_{ik} + e_{ijk}) \\ &= \text{Var}(S_{ij} + e_{ijk}) \\ &= \text{Var}(S_{ij}) + \text{Var}(e_{ijk}) \\ &= \sigma_S^2 + \sigma_e^2\end{aligned}$$

Correlation between observations taken on the same subject:

$$\begin{aligned} \text{Cov}(Y_{ijk}, Y_{ij\ell}) &= \text{Cov}(\mu + \alpha_i + S_{ij} + \tau_k + \gamma_{ik} + e_{ijk}, \\ &\quad \mu + \alpha_i + S_{ij} + \tau_\ell + \gamma_{i\ell} + e_{ij\ell}) \\ &= \text{Cov}(S_{ij} + e_{ijk}, S_{ij} + e_{ij\ell}) \\ &= \text{Cov}(S_{ij}, S_{ij}) + \text{Cov}(S_{ij}, e_{ij\ell}) \\ &\quad + \text{Cov}(e_{ijk}, S_{ij}) + \text{Cov}(e_{ijk}, e_{ij\ell}) \\ &= \text{Var}(S_{ij}) \\ &= \sigma_S^2 \quad \text{for } k \neq \ell. \end{aligned}$$

The correlation between  $Y_{ijk}$  and  $Y_{ij\ell}$  is

$$\frac{\sigma_S^2}{\sigma_S^2 + \sigma_e^2} \equiv \rho$$

Observations taken on different subjects are uncorrelated.

For the set of observations taken on a single subject, we have

$$\text{Var} \begin{bmatrix} Y_{ij1} \\ Y_{ij2} \\ \vdots \\ Y_{ij7} \end{bmatrix} = \begin{bmatrix} \sigma_e^2 + \sigma_S^2 & \sigma_S^2 & \cdots & \sigma_S^2 \\ \sigma_S^2 & \sigma_e^2 + \sigma_S^2 & \cdots & \sigma_S^2 \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_S^2 & \sigma_S^2 & \sigma_S^2 & \sigma_e^2 + \sigma_S^2 \end{bmatrix}$$
$$= \sigma_e^2 I + \sigma_S^2 J$$

This covariance structure is called compound symmetry.

Write this model in the form

$$\mathbf{Y} = X\boldsymbol{\beta} + Z\mathbf{u} + \mathbf{e}$$

$$\begin{bmatrix} Y_{111} \\ Y_{112} \\ \vdots \\ Y_{117} \\ Y_{121} \\ Y_{122} \\ \vdots \\ Y_{127} \\ \vdots \\ Y_{211} \\ Y_{212} \\ \vdots \\ Y_{217} \\ \vdots \\ Y_{3,n_31} \\ Y_{3,n_32} \\ \vdots \\ Y_{3,n_37} \end{bmatrix} = \begin{bmatrix} 1 & 1 & 0 & 0 & 1000000 \\ 1 & 1 & 0 & 0 & 0100000 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 1 & 0 & 0 & 0000001 \\ 1 & 1 & 0 & 0 & 1000000 \\ 1 & 1 & 0 & 0 & 0100000 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 1 & 0 & 0 & 0000001 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 0 & 1 & 0 & 1000000 \\ 1 & 0 & 1 & 0 & 0100000 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 0 & 1 & 0 & 0000001 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 0 & 0 & 1 & 1000000 \\ 1 & 0 & 0 & 1 & 0100000 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & 0 & 0 & 1 & 0000001 \end{bmatrix} \begin{matrix} \mu \\ \alpha_1 \\ \alpha_2 \\ \alpha_3 \\ \tau_1 \\ \tau_2 \\ \tau_3 \\ \tau_4 \\ \tau_5 \\ \tau_6 \\ \tau_7 \\ \gamma_{11} \\ \gamma_{12} \\ \vdots \\ \vdots \\ \gamma_{37} \end{matrix}$$

$$\begin{aligned}
& + \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 1 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ \vdots & \vdots & & \vdots \\ 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ \vdots & \vdots & & \vdots \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ \vdots & \vdots & & \vdots \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 1 \\ 0 & 0 & \cdots & 1 \\ \vdots & \vdots & & \vdots \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 1 \end{bmatrix} \begin{bmatrix} S_{11} \\ S_{12} \\ \vdots \\ \vdots \\ \vdots \\ \vdots \\ S_{3, n_3} \end{bmatrix} + \begin{bmatrix} e_{111} \\ e_{112} \\ \vdots \\ \vdots \\ e_{117} \\ e_{121} \\ e_{122} \\ \vdots \\ e_{127} \\ \vdots \\ \vdots \\ e_{211} \\ e_{212} \\ \vdots \\ \vdots \\ e_{217} \\ \vdots \\ \vdots \\ e_{3, n_3 1} \\ e_{3, n_3 2} \\ \vdots \\ \vdots \\ e_{3, n_3 7} \end{bmatrix}
\end{aligned}$$

In this case:

$$R = \text{Var}(\mathbf{e}) = \sigma_e^2 I_{(7r) \times (7r)},$$

$$G = \text{Var}(\mathbf{u}) = \sigma_S^2 I_{r \times r},$$

where  $r$  is the number of subjects

$$\Sigma = \text{Var}(\mathbf{Y}) = ZGZ^T + R$$

is a block diagonal matrix with one block of the form

$$(\sigma_e^2 I_{7 \times 7} + \sigma_S^2 J_{7 \times 7})$$

for each subject

# Analysis of Mixed Linear Models

$$\mathbf{Y} = X\boldsymbol{\beta} + Z\mathbf{u} + \mathbf{e}$$

where  $X_{n \times p}$  and  $Z_{n \times q}$  are known model matrices and

$$\begin{bmatrix} \mathbf{u} \\ \mathbf{e} \end{bmatrix} \sim N \left( \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix}, \begin{bmatrix} G & 0 \\ 0 & R \end{bmatrix} \right)$$

Then

$$Y \sim N(X\boldsymbol{\beta}, \Sigma)$$

where

$$\Sigma = ZGZ^T + R$$

## Some objectives:

- (i) Inferences about estimable functions of fixed effects
  - ▶ Point estimates
  - ▶ Confidence intervals
  - ▶ Tests of hypotheses
- (ii) Estimation of variance components (elements of  $G$  and  $R$ )
- (iii) Predictions of random effects (blup)
- (iv) Predictions of future observations

# Methods of Estimation

## I. Ordinary Least Squares Estimation:

Normal equations (estimating equations):

$$(X^T X)\mathbf{b} = X^T \mathbf{Y}$$

and solutions have the form

$$\mathbf{b} = (X^T X)^{-1} X^T \mathbf{Y}$$

The Gauss-Markov Theorem cannot be applied because it requires uncorrelated responses. In these models

$$\text{Var}(\mathbf{Y}) = ZGZ^T + R \neq \sigma^2 I$$

Hence, the OLS estimator of an estimable function  $\mathbf{C}^T \boldsymbol{\beta}$  is not necessarily a best linear unbiased estimator (b.l.u.e.).

- The OLS estimator for  $\mathbf{C}^T\boldsymbol{\beta}$  is

$$\mathbf{C}^T\mathbf{b} = \mathbf{C}^T(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\mathbf{Y}$$

where

$$\mathbf{b} = (\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\mathbf{Y}$$

is a solution to the normal equations.

- The OLS estimator  $\mathbf{C}^T\mathbf{b}$  is a linear function of  $\mathbf{Y}$ .
- $E(\mathbf{C}^T\mathbf{b}) = \mathbf{C}^T\boldsymbol{\beta}$
- $\text{Var}(\mathbf{C}^T\mathbf{b}) = \mathbf{C}^T(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T(\mathbf{Z}\mathbf{G}\mathbf{Z}^T + \mathbf{R})\mathbf{X}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{C}$
- If  $\mathbf{Y} \sim N(\mathbf{X}\boldsymbol{\beta}, \mathbf{Z}\mathbf{G}\mathbf{Z}^T + \mathbf{R})$ , then  $\mathbf{C}^T\mathbf{b}$  has a normal distribution with mean  $\mathbf{C}^T\boldsymbol{\beta}$  and covariance matrix

$$\mathbf{C}^T(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T(\mathbf{Z}\mathbf{G}\mathbf{Z}^T + \mathbf{R})\mathbf{X}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{C}$$

## II. Generalized Least Squares (GLS) Estimation:

Suppose

$$E(\mathbf{Y}) = X\boldsymbol{\beta}$$

and also suppose

$$\Sigma = \text{Var}(\mathbf{Y}) = ZGZ^T + R$$

is known. Then a GLS estimator for  $\boldsymbol{\beta}$  is any  $\mathbf{b}$  that minimizes

$$Q(\mathbf{b}) = (\mathbf{Y} - X\mathbf{b})^T \Sigma^{-1} (\mathbf{Y} - X\mathbf{b})$$

The estimating equations are:

$$(X^T \Sigma^{-1} X) \mathbf{b} = X^T \Sigma^{-1} \mathbf{Y}$$

and

$$\mathbf{b}_{GLS} = (X^T \Sigma^{-1} X)^{-1} (X^T \Sigma^{-1} \mathbf{Y})$$

is a solution.

For any estimable function  $C^T\beta$ , the unique b.l.u.e. is

$$C^T\mathbf{b}_{GLS} = C^T(X^T\Sigma^{-1}X)^{-1}X^T\Sigma^{-1}\mathbf{Y}$$

with  $\text{Var}(C^T\mathbf{b}_{GLS}) = C^T(X^T\Sigma^{-1}X)^{-1}C$ . If  $Y \sim N(X\beta, \Sigma)$ , then

$$C^T\mathbf{b}_{GLS} \sim N(C^T\beta, C^T(X^T\Sigma^{-1}X)^{-1}C).$$

When  $G$  and/or  $R$  contain unknown parameters, you could obtain an *approximate BLUE* by replacing the unknown parameters with consistent estimators to obtain

$$\hat{\Sigma} = Z\hat{G}Z^T + \hat{R}$$

and

$$C^T\mathbf{b}_{GLS}^* = C^T(X^T\hat{\Sigma}^{-1}X)^{-1}\hat{\Sigma}^{-1}\mathbf{Y}$$

- $C^T \mathbf{b}_{GLS}^*$  is not a linear function of  $\mathbf{Y}$
- $C^T \mathbf{b}_{GLS}^*$  is not a best linear unbiased estimator (BLUE)
- See Kackar and Harville (1981, 1984) for conditions under which  $C^T \mathbf{b}_{GLS}^*$  is an unbiased estimator for  $C^T \beta$
- $C^T (X^T \hat{\Sigma}^{-1} X)^{-1} C$  tends to *underestimate*  $\text{Var}(C^T \mathbf{b}_{GLS}^*)$  (see Eaton (1984))
- For *large* samples

$$C^T \mathbf{b}_{GLS}^* \sim N(C^T \beta, C^T (X^T \Sigma^{-1} X)^{-1} C)$$

## Variance component estimation

- Estimation of parameters in  $G$  and  $R$
- Crucial to the estimation of estimable functions of fixed effects (e.g.  $E(\mathbf{Y}) = X\beta$ )
- Of interest in its own right (sources of variation in the pigment paste production example)

### Basic Approaches

- (i) ANOVA methods (method of moments): Set observed values of mean squares equal to their expectations and solve the resulting equations.
- (ii) Maximum likelihood estimation (ML)
- (iii) Restricted maximum likelihood estimation (REML)

## I. ANOVA method (Method of Moments)

- Compute an ANOVA table
- Equate mean squares to their expected values
- Solve the resulting equations
- will be discussed later in the examples

## Likelihood-based methods:

Consider the mixed model

$$\mathbf{Y}_{n \times 1} = \mathbf{X}\boldsymbol{\beta}_{p \times 1} + \mathbf{Z}\mathbf{u}_{q \times 1} + \mathbf{e}_{n \times 1}$$

where

$$\begin{bmatrix} \mathbf{u} \\ \mathbf{e} \end{bmatrix} \sim N \left( \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix}, \begin{bmatrix} G & 0 \\ 0 & R \end{bmatrix} \right)$$

Then,

$$\mathbf{Y}_{n \times 1} \sim N(\mathbf{X}\boldsymbol{\beta}, \Sigma)$$

where  $\Sigma = \mathbf{ZGZ}^T + R$

- Maximum Likelihood Estimation
- Restricted Maximum Likelihood Estimation (REML)

## Maximum Likelihood Estimation

Multivariate normal likelihood:

$$L(\beta, \Sigma; \mathbf{Y}) = (2\pi)^{-n/2} |\Sigma|^{-1/2} \exp \left\{ -\frac{1}{2} (\mathbf{Y} - X\beta)^T \Sigma^{-1} (\mathbf{Y} - X\beta) \right\}$$

The log-likelihood function is

$$\begin{aligned} \ell(\beta, \Sigma; \mathbf{Y}) = & -\frac{n}{2} \log(2\pi) - \frac{1}{2} \log(|\Sigma|) \\ & -\frac{1}{2} (\mathbf{Y} - X\beta)^T \Sigma^{-1} (\mathbf{Y} - X\beta) \end{aligned}$$

Given the values of the observed responses,  $\mathbf{Y}$ , find values  $\beta$  and  $\Sigma$  that maximize the log-likelihood function.

This is a difficult computational problem:

- no analytic solution (except in some balanced cases)
- use iterative numerical methods
  - ▶ Need starting values (initial guesses at the values of  $\hat{\beta}$  and  $\hat{\Sigma} = Z\hat{G}Z^T + \hat{R}$ ).
  - ▶ local or global maxima?
  - ▶ what if  $\hat{\Sigma}$  becomes singular or is not positive definite?

- Constrained optimization

- ▶ estimates of variances cannot be negative
- ▶ estimated correlations between -1 and 1
- ▶  $\hat{\Sigma}$ ,  $\hat{G}$ , and  $\hat{R}$  are positive definite (or non-negative definite)

- Large sample distributional properties of estimators

- ▶ consistency
- ▶ normality
- ▶ efficiency\*

\*not guaranteed for ANOVA methods

- Estimates of variance components tend to be too small

Consider a sample  $Y_1, \dots, Y_n$  from a  $N(\mu, \sigma^2)$  distribution. An unbiased estimator for  $\sigma^2$  is

$$S^2 = \frac{1}{n-1} \sum_{j=1}^n (Y_j - \bar{Y})^2$$

The MLE for  $\sigma^2$  is

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{j=1}^n (Y_j - \bar{Y})^2$$

with

$$E(\hat{\sigma}^2) = \left( \frac{n-1}{n} \right) \sigma^2 < \sigma^2$$

Note that  $S^2$  and  $\hat{\sigma}^2$  are based on *error contrasts*

$$\begin{aligned} e_1 &= Y_1 - \bar{Y} = \left(\frac{n-1}{n}, -\frac{1}{n}, \dots, -\frac{1}{n}\right) \mathbf{Y} \\ &\vdots \\ e_n &= Y_n - \bar{Y} = \left(-\frac{1}{n}, -\frac{1}{n}, \dots, -\frac{1}{n}, \frac{n-1}{n}\right) \mathbf{Y} \end{aligned}$$

whose distribution does not depend on

$$\mu = E(Y_j) .$$

When  $\mathbf{Y} \sim N(\mu \mathbf{1}, \sigma^2 I)$ ,

$$\mathbf{e} = \begin{bmatrix} e_1 \\ \vdots \\ e_n \end{bmatrix} = (I - P_1) \mathbf{Y} \sim N[\mathbf{0}, \sigma^2(I - P_1)]$$

- The MLE  $\hat{\sigma}^2 = \frac{1}{n} \sum_{j=1}^n e_j^2$  fails to acknowledge that  $\mathbf{e}$  is restricted to an  $(n - 1)$ -dimensional space, i.e.,  $\sum_{j=1}^n e_j = 0$ .
- The MLE fails to make the appropriate adjustment in *degrees of freedom* needed to obtain an unbiased estimator for  $\sigma^2$ .

Example: Suppose  $n = 4$  and  $\mathbf{Y} \sim N(\mu \mathbf{1}, \sigma^2 I)$ .

Then

$$\mathbf{e} = \begin{bmatrix} Y_1 - \bar{Y} \\ Y_2 - \bar{Y} \\ Y_3 - \bar{Y} \\ Y_4 - \bar{Y} \end{bmatrix} = (I - P_1)\mathbf{Y} \sim N \left[ 0, \underline{\sigma^2(I - P_1)} \right]$$

↑

This covariance matrix is singular.

Here,  $m = \text{rank}(I - P_1) = n - 1 = 3$ .

Define

$$\mathbf{r} = M\mathbf{e} = M(I - P_X)\mathbf{Y}$$

where

$$M = \begin{bmatrix} 1 & 1 & -1 & -1 \\ 1 & -1 & 1 & -1 \\ 1 & -1 & -1 & 1 \end{bmatrix}$$

has row rank equal to

$$m = \text{rank}(I - P_X).$$

Then

$$\mathbf{r} = \begin{bmatrix} r_1 \\ r_2 \\ r_3 \end{bmatrix} = \begin{bmatrix} Y_1 + Y_2 - Y_3 - Y_4 \\ Y_1 - Y_2 + Y_3 - Y_4 \\ Y_1 - Y_2 - Y_3 + Y_4 \end{bmatrix}$$

$$= M(I - P_1)\mathbf{Y} \sim N(\mathbf{0}, \underline{\sigma^2 M(I - P_1)M^T})$$

↑  
call this  $\sigma^2 W$

### Restricted Likelihood function:

$$L(\sigma^2; \mathbf{r}) = \frac{1}{(2\pi)^{M/2} |\sigma^2 W|^{1/2}} e^{-\frac{1}{2\sigma^2} \mathbf{r}^T W^{-1} \mathbf{r}}$$

### Restricted Log-likelihood:

$$\begin{aligned} \ell(\sigma^2; \mathbf{r}) = & -\frac{m}{2} \log(2\pi) - \frac{m}{2} \log(\sigma^2) \\ & -\frac{1}{2} \log|W| - \frac{1}{2\sigma^2} \mathbf{r}^T W^{-1} \mathbf{r} \end{aligned}$$

(Note that  $|\sigma^2 W| = (\sigma^2)^m |W|$ )

(Restricted) likelihood equation:

$$0 = \frac{\partial \ell(\sigma^2; \mathbf{r})}{\partial \sigma^2} = \frac{-m}{2\sigma^2} + \frac{1}{2(\sigma^2)^2} \mathbf{r}^T W^{-1} \mathbf{r}$$

Solution (REML estimator for  $\sigma^2$ ):

$$\begin{aligned}\hat{\sigma}_{REML}^2 &= \frac{1}{m} \mathbf{r}^T W^{-1} \mathbf{r} \\ &= \frac{1}{m} \mathbf{Y}^T \underbrace{(I - P_1)^T M^T (M(I - P_1)M^T)^{-1} M(I - P_1) \mathbf{Y}}\end{aligned}$$

↗

This is a projection of  $\mathbf{Y}$  onto the column space of  $M(I - P_1)$  which is the column space of  $I - P_1$

$$\begin{aligned}&= \frac{1}{m} \mathbf{Y}^T (I - P_1) \mathbf{Y} \\ &= \frac{1}{n-1} \sum_{j=1}^n (Y_j - \bar{Y})^2 = S^2\end{aligned}$$

## REML (Restricted Maximum Likelihood) estimation

- Estimate parameters in

$$\Sigma = ZGZ^T + R$$

by maximizing the part of the likelihood that does not depend on  $E(\mathbf{Y}) = X\beta$

- Maximize a likelihood function for *error contrasts*
  - ▶ linear combinations of observations that do not depend on  $X\beta$
  - ▶ Find a set of

$$n - \text{rank}(X)$$

linearly independent *error contrasts*

Mixed (normal-theory) model:

$$\mathbf{Y} = X\boldsymbol{\beta} + Z\mathbf{u} + \mathbf{e}$$

where  $\begin{bmatrix} \mathbf{u} \\ \mathbf{e} \end{bmatrix} \sim N\left(\begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix}, \begin{bmatrix} G & 0 \\ 0 & R \end{bmatrix}\right)$

Then

$$L\mathbf{Y} = L(X\boldsymbol{\beta} + Z\mathbf{u} + \mathbf{e}) = LX\boldsymbol{\beta} + LZ\mathbf{u} + L\mathbf{e}$$

is invariant to  $X\boldsymbol{\beta}$  if and only if  $LX = 0$ . But  $LX = 0$  if and only if

$$L = M(I - P_X)$$

for some M. (Here  $P_X = X(X^T X)^{-1}X^T$ )

To avoid losing information we must have

$$\begin{aligned}\text{row rank}(M) &= n - \text{rank}(X) \\ &= n - p\end{aligned}$$

Then a set of  $n - p$  error contrasts is

$$\begin{aligned}\mathbf{r} &= M(I - P_X)\mathbf{Y} \\ &\sim N_{n-p}(\mathbf{0}, \underbrace{M(I - P_X)\Sigma^{-1}(I - P_X)M^T})\end{aligned}$$

  
call this  $W$ ,  
then  $\text{rank}(W) = n - p$   
and  $W^{-1}$  exists.

The *Restricted* likelihood is

$$L(\Sigma; \mathbf{r}) = \frac{1}{(2\pi)^{(n-p)/2} |W|^{1/2}} e^{-\frac{1}{2} \mathbf{r}^T W^{-1} \mathbf{r}}$$

The resulting log-likelihood is

$$\begin{aligned} \ell(\Sigma; \mathbf{r}) = & \frac{-(n-p)}{2} \log(2\pi) - \frac{1}{2} \log |W| \\ & - \frac{1}{2} \mathbf{r}^T W^{-1} \mathbf{r} \end{aligned}$$

For any  $M_{(n-p) \times n}$  with row rank equal to

$$n - p = n - \text{rank}(X)$$

the log-likelihood can be expressed in terms of

$$\mathbf{e} = (I - X(X\Sigma^{-1}X^T)^{-1}X^T\Sigma^{-1})\mathbf{Y}$$

as

$$\begin{aligned}\ell(\Sigma; \mathbf{e}) = & \text{constant} - \frac{1}{2} \log(|\Sigma|) \\ & - \frac{1}{2} \log(|X_*^T \Sigma^{-1} X_*|) - \frac{1}{2} \mathbf{e}^T \Sigma^{-1} \mathbf{e}\end{aligned}$$

where  $X_*$  is any set of  $p = \text{rank}(X)$  linearly independent columns of  $X$ . Denote the resulting REML estimators as

$$\hat{G}, \quad \hat{R} \quad \text{and} \quad \hat{\Sigma} = Z\hat{G}Z^T + \hat{R}$$

## Estimation of fixed effects

For any estimable function  $C\beta$ , the **blue** is the generalized least squares estimator

$$C\mathbf{b}_{GLS} = C(X^T \Sigma^{-1} X)^{-1} X^T \Sigma^{-1} \mathbf{Y}$$

Using the REML estimator for

$$\Sigma = ZGZ^T + R$$

an approximation is

$$C\hat{\beta} = C(X^T \hat{\Sigma}^{-1} X)^{-1} X^T \hat{\Sigma}^{-1} \mathbf{Y}$$

and for *large* samples:

$$C\hat{\beta} \sim N(C\beta, C(X^T \Sigma^{-1} X)^{-1} C^T)$$

## Prediction of random effects

Given the observed responses  $\mathbf{Y}$ , predict the value of  $\mathbf{u}$ .

For our model,

$$\begin{bmatrix} \mathbf{u} \\ \mathbf{e} \end{bmatrix} \sim N \left( \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix}, \begin{bmatrix} G & 0 \\ 0 & R \end{bmatrix} \right).$$

Then (from result 4.1)

$$\begin{aligned} \begin{bmatrix} \mathbf{u} \\ \mathbf{Y} \end{bmatrix} &= \begin{bmatrix} \mathbf{u} \\ X\beta + Z\mathbf{u} + \mathbf{e} \end{bmatrix} \\ &= \begin{bmatrix} \mathbf{0} \\ X\beta \end{bmatrix} + \begin{bmatrix} I & 0 \\ Z & I \end{bmatrix} \begin{bmatrix} \mathbf{u} \\ \mathbf{e} \end{bmatrix} \\ &\sim N \left( \begin{bmatrix} \mathbf{0} \\ X\beta \end{bmatrix}, \begin{bmatrix} G & GZ^T \\ ZG & ZGZ^T + R \end{bmatrix} \right) \end{aligned}$$

The Best Linear Unbiased Predictor (BLUP) is the b.l.u.e. for

$$E(\mathbf{u}|\mathbf{Y}) = E(\mathbf{u}) + (GZ^T)(ZGZ^T + R)^{-1}(\mathbf{Y} - E(\mathbf{Y}))$$

$$= \mathbf{0} + GZ^T(ZGZ^T + R)^{-1}(\mathbf{Y} - X\beta)$$

↑

substitute the b.l.u.e. for  $X\beta$

$$X\mathbf{b}_{GLS} = X(X^T\Sigma^{-1}X)^{-1}X^T\Sigma^{-1}\mathbf{Y}$$

Then, the BLUP for  $\mathbf{u}$  is

$$\begin{aligned} BLUP(\mathbf{u}) &= GZ^T\Sigma^{-1}(\mathbf{Y} - X\mathbf{b}_{GLS}) \\ &= GZ^T\Sigma^{-1}(I - X(X^T\Sigma^{-1}X)^{-1}X^T\Sigma^{-1})\mathbf{Y}, \end{aligned}$$

when  $G$  and  $\Sigma = ZGZ^T + R$  are known.

Substituting REML estimators  $\hat{G}$  and  $\hat{R}$  for  $G$  and  $R$ , an approximate BLUP for  $\mathbf{u}$  is

$$\begin{aligned}\hat{\mathbf{u}} &= \hat{G}Z^T\hat{\Sigma}^{-1}(I - X(X^T\hat{\Sigma}^{-1}X)^{-1}X^T\hat{\Sigma}^{-1})\mathbf{Y} \\ &= \hat{G}Z^T\hat{\Sigma}^{-1}(\mathbf{Y} - \underline{X\hat{\beta}})\end{aligned}$$

For *large* samples, the distribution of  $\hat{\mathbf{u}}$  is approximately multivariate normal with mean vector  $\mathbf{0}$  and covariance matrix

$$GZ^T\Sigma^{-1}(I - P)\Sigma(I - P)\Sigma^{-1}ZG$$

where

$$P = X(X^T\Sigma^{-1}X)^{-1}X^T\Sigma^{-1}$$

Given estimates  $\hat{G}$ ,  $\hat{R}$  and  $\hat{\Sigma} = Z\hat{G}Z^T + \hat{R}$ ,  $\hat{\beta}$  and  $\hat{\mathbf{u}}$  provide a solution to the mixed model equations:

$$\begin{bmatrix} X^T \hat{R}^{-1} X & X^T \hat{R}^{-1} Z \\ Z^T \hat{R}^{-1} X & Z^T \hat{R}^{-1} Z + \hat{G}^{-1} \end{bmatrix} \begin{bmatrix} \hat{\beta} \\ \hat{\mathbf{u}} \end{bmatrix} = \begin{bmatrix} X^T \hat{R}^{-1} \mathbf{Y} \\ Z^T \hat{R}^{-1} \mathbf{Y} \end{bmatrix}$$

A generalized inverse of

$$\begin{bmatrix} X^T \hat{R}^{-1} X & X^T \hat{R}^{-1} Z \\ Z^T \hat{R}^{-1} X & Z^T \hat{R}^{-1} Z + \hat{G}^{-1} \end{bmatrix}$$

is used to approximate the covariance matrix for  $\begin{bmatrix} \hat{\beta} \\ \hat{\mathbf{u}} \end{bmatrix}$

## Example 9.1: Penicillin production

$$Y_{ij} = \mu + \alpha_i + \beta_j + e_{ij}$$

where

$$\beta_j \sim NID(0, \sigma_\beta^2)$$

and

$$e_{ij} \sim NID(0, \sigma_e^2)$$

<u>Source of Variation</u>	<u>d.f.</u>	<u>Sums of Squares</u>
Blocks	4	$a \sum_{j=1}^b (\bar{Y}_{.j} - \bar{Y}_{..})^2 = SS_{blocks}$
Processes	3	$b \sum_{i=1}^a (\bar{Y}_{1.} - \bar{Y}_{..})^2 = SS_{processes}$
error	12	$\sum_{i=1}^a \sum_{j=1}^b (Y_{ij} - \bar{Y}_{1.} - \bar{Y}_{.j} + \bar{Y}_{..})^2 = SSE$
C. total	19	$\sum_{i=1}^a \sum_{j=1}^b (Y_{ij} - \bar{Y}_{..})^2$

- Variance Component Estimation (ANOVA method)

Start at the bottom:

$$MS_{error} = \frac{SSE}{(a-1)(b-1)}$$

$$E(MS_{error}) = \sigma_e^2$$

Then an unbiased estimator for  $\sigma_e$  is

$$\hat{\sigma}_e^2 = MS_{error}$$

Next, consider the mean square for the random block effects:

$$MS_{blocks} = \frac{SS_{blocks}}{b - 1}$$

$$E(MS_{blocks}) = \sigma_e^2 + a\sigma_\beta^2$$

↑  
number of  
observations  
for each block

Then,

$$\begin{aligned}\sigma_\beta^2 &= \frac{E(MS_{blocks}) - \sigma_e^2}{a} \\ &= \frac{E(MS_{blocks}) - E(MS_{error})}{a}\end{aligned}$$

An unbiased estimator for  $\sigma_\beta^2$  is

$$\hat{\sigma}_\beta^2 = \frac{MS_{blocks} - MS_{error}}{a}$$

For the penicillin data

$$\hat{\sigma}_e^2 = MS_{error} = 18.83$$

$$\begin{aligned}\hat{\sigma}_\beta^2 &= \frac{MS_{blocks} - MS_{error}}{4} \\ &= \frac{66.0 - 18.83}{4} = 11.79\end{aligned}$$

$$\begin{aligned}\widehat{Var}(Y_{ij}) &= \hat{\sigma}_\beta^2 + \hat{\sigma}_e^2 \\ &= 11.79 + 18.83 = 30.62\end{aligned}$$

- Inferences about treatment means:

$$Y_{ij} = \mu + \alpha_i + \beta_j + e_{ij}$$

Consider the sample mean (one observation for each treatment in each block):

$$\bar{Y}_{i.} = \frac{1}{b} \sum_{j=1}^b Y_{ij}$$

$$E(\bar{Y}_{i.}) = \begin{cases} \mu + \alpha_i & \text{for random} \\ & \text{block effects} \\ & \beta_j \sim NID(0, \sigma_\beta^2) \\ \mu + \alpha_i + \frac{1}{b} \sum_{j=1}^b \beta_j & \text{for fixed} \\ & \text{block effects} \end{cases}$$

and

$$\begin{aligned} \text{Var}(\bar{Y}_{i.}) &= \text{Var}\left(\frac{1}{b} \sum_{j=1}^b Y_{ij}\right) \\ &= \frac{1}{b^2} \sum_{j=1}^b \text{Var}(Y_{ij}) \\ &= \begin{cases} \frac{1}{b}(\sigma_e^2 + \sigma_b^2) & \text{random block effect} \\ \frac{1}{b}(\sigma_e^2) & \text{fixed block effect} \end{cases} \end{aligned}$$

**Fixed** additive block effects:

### Confidence Intervals

$$S_{\bar{Y}_{i.}}^2 = \frac{1}{b} \hat{\sigma}_e^2 = \frac{1}{b} MS_{error}$$

The standard error for  $\bar{Y}_{i.}$  is

$$S_{\bar{Y}_{i.}} = \sqrt{\frac{1}{b} MS_{error}} = 1.941$$

A  $(1 - \alpha) \times 100\%$  confidence interval for

$$\mu + \alpha_i + \frac{1}{b} \sum_{j=1}^b \beta_j$$

is

$$\bar{Y}_{i.} \pm t_{(a-1)(b-1), \frac{\alpha}{2}} \sqrt{\frac{1}{b} MS_{error}}$$

### t-tests:

Reject  $H_0 : \mu + \alpha_i + \frac{1}{b} \sum_{j=1}^b \beta_j = d$  if

$$|t| = \frac{|\bar{Y}_{i.} - d|}{\sqrt{\frac{1}{b} MS_{error}}} > t_{(a-1)(b-1), \frac{\alpha}{2}}$$

- This is what is done by the LSMEANS option in the GLM procedure in SAS, even when you specify RANDOM BATCH;
- This is what is done by the MIXED procedure in SAS when batch effects are not random

Random additive block effects:

$$\begin{aligned} S_{\bar{Y}_{i.}}^2 &= \frac{1}{b}(\hat{\sigma}_e^2 + \hat{\sigma}_\beta^2) \\ &= \frac{1}{b} \left( MS_{error} + \frac{MS_{blocks} - MS_{error}}{a} \right) \\ &= \frac{a-1}{ab} MS_{error} + \frac{1}{ab} MS_{blocks} \\ &= \frac{1}{ab(b-1)} [SS_{error} + SS_{blocks}] \end{aligned}$$

$\sigma_e^2 \chi_{(a-1)(b-1)}^2$   
 $\nearrow$

$(\sigma_e^2 + a\sigma_\beta^2) \chi_{(b-1)}^2$   
 $\nwarrow$

Hence, the distribution of  $S_{\bar{Y}_{i.}}^2$  is not a multiple of a central chi-square random variable.

## Confidence Interval

Standard error for  $\bar{Y}_{i.}$  is

$$S_{\bar{Y}_{i.}} = \sqrt{\frac{a-1}{ab} MS_{error} + \frac{1}{ab} MS_{blocks}} = 2.4749$$

An approximate  $(1 - \alpha) \times 100\%$  confidence interval for  $\mu + \alpha_i$  is

$$\bar{Y}_{i.} \pm t_{\nu, \frac{\alpha}{2}} \sqrt{\frac{a-1}{ab} MS_{error} + \frac{1}{ab} MS_{blocks}}$$

where

$$\begin{aligned} \nu &= \frac{\left[ \frac{a-1}{ab} MS_{error} + \frac{1}{ab} MS_{blocks} \right]^2}{\frac{\left( \frac{a-1}{ab} MS_{error} \right)^2}{(a-1)(b-1)} + \frac{\left( \frac{1}{ab} MS_{blocks} \right)^2}{b-1}} = \frac{\left[ \frac{4-1}{(4)(5)} MS_{error} + \frac{1}{ab} MS_{blocks} \right]^2}{\frac{\left( \frac{a-1}{ab} MS_{error} \right)^2}{(a-1)(b-1)} + \frac{\left( \frac{1}{ab} MS_{blocks} \right)^2}{b-1}} \\ &= 11.075 \end{aligned}$$

## Result 9.1: Cochran-Satterthwaite approximation

Suppose  $MS_1, MS_2, \dots, MS_k$  are mean squares with

- independent distributions
- degrees of freedom =  $df_i$
- $\frac{(df_i)MS_i}{E(MS_i)} \sim \chi_{df_i}^2$

Then, for positive constants

$$a_i > 0, \quad i = 1, 2, \dots, k$$

the distribution of

$$S^2 = a_1 MS_1 + a_2 MS_2 + \dots + a_k MS_k$$

is approximated by

$$\frac{vS^2}{E(S^2)} \sim \chi_v^2$$

where

$$v = \frac{[E(S^2)]^2}{\frac{[a_1 E(MS_1)]^2}{df_1} + \dots + \frac{[a_k E(MS_k)]^2}{df_k}}$$

is the value for the degrees of freedom.

In practice, the degrees of freedom are evaluated as

$$V = \frac{[S^2]^2}{\frac{(a_1 MS_1)^2}{df_1} + \dots + \frac{(a_k MS_k)^2}{df_k}}$$

These are called the Cochran- Satterthwaite degrees of freedom.

Cochran, W.G. (1951) Testing a Linear Relation among Variances, Biometrics 7, 17-32.

## Difference between two means:

$$\begin{aligned}E(\bar{Y}_{i.} - \bar{Y}_{k.}) &= E\left(\frac{1}{b} \sum_{j=1}^b Y_{ij} - \frac{1}{b} \sum_{j=1}^b Y_{kj}\right) \\&= E\left(\frac{1}{b} \sum_{j=1}^b (Y_{ij} - Y_{kj})\right) \\&= E\left(\frac{1}{b} \sum_{j=1}^b (\mu + \alpha_i + \beta_j + \epsilon_{ij} - \mu - \alpha_k - \beta_j - \epsilon_{kj})\right) \\&= \alpha_i - \alpha_k + \frac{1}{b} \sum_{j=1}^b \underline{E(\epsilon_{ij} - \epsilon_{kj})} \\&= \alpha_i - \alpha_k = (\mu + \alpha_i) - (\mu + \alpha_k)\end{aligned}$$

whether block effects are fixed or random.

$$\begin{aligned}
 \text{Var}(\bar{Y}_{i.} - \bar{Y}_{k.}) &= \text{Var}\left(\alpha_i - \alpha_k + \frac{1}{b} \sum_{j=1}^b (\epsilon_{ij} - \epsilon_{kj})\right) \\
 &= \frac{1}{b^2} \sum_{j=1}^b \text{Var}(\epsilon_{ij} - \epsilon_{kj}) = \frac{2\sigma_e^2}{b}
 \end{aligned}$$

The standard error for  $\bar{Y}_{i.} - \bar{Y}_{k.}$  is

$$S_{\bar{Y}_{i.} - \bar{Y}_{k.}} = \sqrt{\frac{2MS_{\text{error}}}{b}}$$

A  $(1 - \alpha) \times 100\%$  confidence interval for  $\alpha_i - \alpha_j$  is

$$(\bar{Y}_{i.} - \bar{Y}_{k.}) \pm t_{\underline{(a-1)(b-1)}, \frac{\alpha}{2}} \sqrt{\frac{2MS_{\text{error}}}{b}}$$

$\uparrow$   
 d.f. for  $MS_{\text{error}}$

t-test:

Reject  $H_0 : \alpha_i - \alpha_k = 0$  if

$$|t| = \frac{|\bar{Y}_{i.} - \bar{Y}_{j.}|}{\sqrt{\frac{2MS_{error}}{b}}} > t_{(a-1)(b-1), \frac{\alpha}{2}}$$

↑  
d.f. for  $MS_{error}$

**Refer the slide9\_penciln.pdf.**

## Example 9.2 Pigment production

In this example the main objective is the estimation of the variance components

### ANOVA Table

<u>Source of Variation</u>	<u>d.f.</u>	<u>MS</u>	<u>E(MS)</u>
Batches	$15-1=14$	86.495	$\sigma_e^2 + 2\sigma_\delta^2 + 4\sigma_\beta^2$
Samples in Batches	$15(2-1)=15$	57.983	$\sigma_e^2 + 2\sigma_\delta^2$
Tests in Samples	$(30)(2-1)=30$	0.917	$\sigma_e^2$

- Estimates of variance components:

$$\hat{\sigma}_e^2 = MS_{tests} = 0.917$$

$$\hat{\sigma}_\delta^2 = \frac{MS_{samples} - MS_{tests}}{2} = 28.533$$

$$\hat{\sigma}_\beta^2 = \frac{MS_{batches} - MS_{samples}}{4} = 7.128$$

- Estimation of  $\mu = E(Y_{ijk})$ :

$$\hat{\mu} = \bar{Y}_{...} = \frac{1}{bsr} \sum_{i=1}^b \sum_{j=1}^s \sum_{k=1}^r Y_{ijk}$$

$$E(\bar{Y}_{...}) = \mu, \quad \text{Var}(\bar{Y}_{...}) = \frac{1}{bsr} (\sigma_e^2 + r\sigma_\delta^2 + Sr\sigma_\beta^2)$$

Standard error:

$$\begin{aligned} S_{\bar{Y}_{...}} &= \sqrt{\frac{1}{bsr} (\hat{\sigma}_e^2 + r\hat{\sigma}_\delta^2 + sr\hat{\sigma}_\beta^2)} \\ &= \sqrt{\frac{1}{bsr} (MS_{Batches})} \\ &= \sqrt{\frac{86.495}{60}} = 1.4416 \end{aligned}$$

A 95% confidence interval for  $\mu$

$$\bar{Y}_{...} \pm t_{14,.025} S_{\bar{Y}_{...}}$$

  
df for  $MS_{Batches}$

Here,  $t_{14,.025} = 2.510$  and the confidence interval is

$$26.783 \pm (2.510)(1.4416)$$

$$\Rightarrow (23.16, 30.40)$$

## Some comments on the variance components estimation

- Properties of ANOVA methods for variance component estimation:
  - (i) Broad applicability
    - ▶ easy to compute in balanced cases
    - ▶ ANOVA is widely known
    - ▶ not required to completely specify distributions for random effects
  - (ii) Unbiased estimators
  - (iii) Sampling distribution is not exactly known, even under the usual normality assumptions (except for  $\hat{\sigma}_e^2 = MS_{error}$ )

- (iv) May produce negative estimates of variances
- (v) REML estimates have the same values
  - ▶ in simple balanced cases
  - ▶ when ANOVA estimates of variance components are inside the parameter space
- (vi) For unbalanced studies, there may be no *natural* way to choose

$$\hat{\sigma}^2 = \sum_{i=1}^k a_i MS_i$$

## Result 10.2:

If  $MS_1, MS_2, \dots, MS_k$  are distributed independently with

$$\frac{(df_i)MS_i}{E(MS_i)} \sim \chi_{df_i}^2$$

and constants  $a_i > 0, i = 1, 2, \dots, k$  are selected so that

$$\hat{\sigma}^2 = \sum_{i=1}^k a_i MS_i$$

has expectation  $\sigma^2$ , then

$$Var(\hat{\sigma}^2) = 2 \sum_{i=1}^k \frac{a_i^2 [E(MS_i)]^2}{df_i}$$

and an unbiased estimator of this variance is

$$\widehat{Var}(\hat{\sigma}^2) = \frac{2a_i^2 MS_i^2}{(df_i + 2)}$$

A *standard error* for

$$\hat{\sigma}^2 = \sum_{i=1}^k a_i MS_i$$

could be reported as

$$S_{\hat{\sigma}^2} = \sqrt{2 \sum_{i=1}^k \frac{a_i^2 MS_i^2}{(df_i + 2)}}$$

Using the Cochran-Satterthwaite approximation (Result 9.1), an approximate  $(1 - \alpha) \times 100\%$  confidence interval for  $\sigma^2$  could be constructed as:

$$\begin{aligned} 1 - \alpha &\doteq Pr \left\{ \chi_{\nu, 1-\alpha/2}^2 \leq \frac{v\hat{\sigma}^2}{\sigma^2} \leq \chi_{\nu, \alpha/2}^2 \right\} \\ &= Pr \left\{ \frac{v\hat{\sigma}^2}{\chi_{\nu, \alpha/2}^2} \leq \sigma^2 \leq \frac{v\hat{\sigma}^2}{\chi_{\nu, 1-\alpha/2}^2} \right\} \end{aligned}$$

where  $\hat{\sigma}^2 = \sum_{i=1}^k a_i MS_i$  and

$$v = \frac{\left[ \sum_{i=1}^k a_i MS_i \right]^2}{\sum_{i=1}^k \frac{[a_i MS_i]^2}{df_i}}$$

**Refer the slide9\_pigment.pdf.**

### Example 9.3 A split-plot experiment with whole plots arranged in blocks.

Model with random block effects:

$$Y_{ijk} = \mu + \alpha_i + \beta_j + \eta_{ij} + \gamma_k + \delta_{ik} + e_{ijk},$$

$$i = 1, \dots, a, \quad j = 1, \dots, r, \quad k = 1, \dots, b,$$

$Y_{ijk} \Rightarrow$  observed yield for the  $k$ -th inoculant applied to the  $i$ -th cultivar in the  $j$ -th field

$\alpha_i \Rightarrow$  fixed cultivar effect

$\gamma_k \Rightarrow$  fixed inoculant effect

$\delta_{ik} \Rightarrow$  cultivar\*inoculant interaction

- ANOVA table:

Source of Variation	df	SS
Blocks	$r - 1 = 3$	25.32
Cultivars	$a - 1 = 1$	2.41
Whole Plot error (Block $\times$ cultivar interaction)	$(r-1)(a-1)=3$	9.48
Innoculants	$b - 1 = 2$	118.18
Cult. $\times$ Innoc.	$(a - 1)(b - 1) = 2$	1.83
Sub-plot error	12	8.465
Corrected total	23	165.673

- ANOVA table - Continued:

Source of Variation	df	MS	$E(MS)$
Blocks	3	8.44	$\sigma_e^2 + b\sigma_w^2 + ba\sigma_\beta^2$
Cultivars	1	2.41	$\sigma_e^2 + b\sigma_w^2 + (i)$
Whole Plot error (Block $\times$ cult. interaction)	3	3.16	$\sigma_e^2 + b\sigma_w^2$
Innoculants	2	59.09	$\sigma_e^2 + (ii)$
Cult. $\times$ Innoc.	2	0.91	$\sigma_e^2 + (iii)$
Sub-plot error	12	0.705	$\sigma_e^2$
Corrected total	23		

- ANOVA table - Continued:

(i)

$$\frac{br \sum_{i=1}^a (\alpha_i + \bar{\delta}_{i.} - \bar{\alpha}_{.} - \bar{\delta}_{..})^2}{a - 1}$$

(ii)

$$\frac{ar \sum_{k=1}^b (\gamma_k + \bar{\delta}_{.k} - \bar{\gamma}_{.} - \bar{\delta}_{..})^2}{b - 1}$$

(iii)

$$\frac{r \sum_i \sum_k (\delta_{ik} - \bar{\delta}_{i.} - \bar{\delta}_{.k} + \bar{\delta}_{..})^2}{(a - 1)(b - 1)}$$

**Refer the slide9\_grass.pdf.**

## Standard errors for sample means

- Whole plot factor

$$\begin{aligned} \text{Var}(\bar{Y}_{i..}) &= \text{Var}\left(\frac{\sum_j \sum_k (\mu + \alpha_i + \beta_j + \eta_{ij} + \gamma_k + \delta_{ik} + e_{ijk})}{rb}\right) \\ &= \text{Var}\left(\frac{1}{r} \sum_{j=1}^r \beta_j\right) + \text{Var}\left(\frac{1}{r} \sum_{j=1}^r \eta_{ij}\right) + \text{Var}\left(\frac{1}{br} \sum_{j=1}^r \sum_{k=1}^b e_{ijk}\right) \\ &= \frac{\sigma_\beta^2}{r} + \frac{\sigma_w^2}{r} + \frac{\sigma_e^2}{rb} \\ &= \frac{\sigma_e^2 + b\sigma_w^2 + b\sigma_\beta^2}{rb} \end{aligned}$$

## Estimation:

$$\hat{\sigma}_e^2 = MS_{error} = .7054$$

$$\hat{\sigma}_w^2 = \frac{MS_{block \times Cult} - MS_{error}}{3} = .8182$$

$$\hat{\sigma}_\beta^2 = \frac{MS_{blocks} - MS_{block \times cult}}{6} = .8800$$

$$\begin{aligned} S_{\bar{Y}_{i..}}^2 &= \frac{\hat{\sigma}_e^2 + b\hat{\sigma}_w^2 + b\hat{\sigma}_\beta^2}{rb} \\ &= \frac{1}{rb} \left[ \left( \frac{a-1}{a} \right) MS_{block * Cult} + \frac{1}{a} MS_{blocks} \right] \\ &= 0.48333 \quad (\text{and } S_{\bar{Y}_{i..}} = 0.6952) \end{aligned}$$

with

$$\begin{aligned} d.f. &= \frac{\left[ \frac{a-1}{a} MS_{block*cult} + \frac{1}{a} MS_{blocks} \right]^2}{\frac{\left[ \frac{a-1}{a} MS_{blocks*cult} \right]^2}{(a-1)(r-1)} + \frac{\left[ \frac{1}{a} MS_{blocks} \right]^2}{r-1}} \\ &= 4.97 \end{aligned}$$

- Difference in levels of the whole plot factor

$$\begin{aligned}
 \text{Var}(\bar{Y}_{i..} - \bar{Y}_{s..}) &= \text{Var}\left(\frac{1}{rb} \sum_j \sum_k (Y_{ijk} - Y_{sjk})\right) \\
 &= \text{Var}\left(\alpha_i - \alpha_s + \frac{1}{r} \sum_j (\eta_{ij} - \eta_{sj}) + \frac{1}{b} \sum_k (\delta_{ik} - \delta_{sk}) \right. \\

$$\begin{aligned}
&= \text{Var}(\delta_{ik} - \delta_{i\ell} - \delta_{sk} + \delta_{s\ell} \\
&\quad + \frac{1}{r} \sum_j (e_{ijk} - e_{ij\ell} - e_{sjk} + e_{sj\ell})) \\
&= \frac{4\sigma_e^2}{r}
\end{aligned}$$

## Estimation:

$$\hat{\sigma}_e^2 = MS_{error} = .7054$$

$$S_{\bar{Y}_{i.k} - \bar{Y}_{i.l} - \bar{Y}_{s.k} + \bar{Y}_{s.l}}^2 = \frac{4}{r}(\hat{\sigma}_e^2)$$

$$= \frac{4}{r}MS_{error}$$

$$= 0.705$$

and

$$S_{\bar{Y}_{i.k} - \bar{Y}_{i.l} - \bar{Y}_{s.k} + \bar{Y}_{s.l}} = 0.5396$$

with

$$d.f. = 12$$
